BREAST ASYMMETRY IN WOMEN REQUESTING PLASTIC SURGERY OF THE BREAST

Norma I. Cruz, MD

Division of Plastic Surgery
University of Puerto Rico

Nothing to Disclose
Is the high frequency of breast asymmetry restricted to augmentation patients?
Method

Clinical Study

Breast measurements of 244 consecutive women, who had no prior breast surgery, were prospectively recorded in a database. Comparisons were made between the right and left breast regarding symmetry of the nipple areola complex, breast mound and chest wall.
The patients were classified into three groups according to the presenting breast problem.

- **Hypoplastic Breasts** (Augmentation)
- **Macromastia** (Breast Reduction)
- **Ptotic Breasts** (Mastopexy & Implants)
Asymmetries

Nipple-areola complex
• Position
• Size
Asymmetries

Breast Mound
• Volume
• Base
• Inframammary fold (IMF)
Asymmetries

Chest wall
• Pectus excavatum/carinatum
• Rib flaring

Overall 91% of the women had at least one type of preoperative breast asymmetry.
Breast asymmetries occur in the majority of women and these findings are similar among the different groups. Since they are often unaware of the problem, they should be informed of the presence of the asymmetry and how this may affect the surgical outcome.
